"From the President:  
Call for Accelerator Section Abstracts"  
Marcia Maria Campos Torres,  
mtorres@slac.stanford.edu  
SLAC National Accelerator Laboratory  

This year we are trying a new approach to the Accelerator Section’s session at the annual meeting and providing the final deadline upfront, with an explanation as to how talks for the annual meeting are determined. The abstract submittal deadline is 28 February 2019.

This is a special meeting for the accelerator section, we will have special invited speaker(s) to discuss the history of light sources, and we are kindly requesting your contribution with as many papers as you can submit.

Please submit your abstract through the HPS website at this link.

Your President,  
Marcia Torres

"Precision measurements of the proton’s weak charge narrows the search for new physics"  
Provided by Bob May, may@jlab.org  
Jefferson Lab  

NEWPORT NEWS, VA – A new result from the Q-weak experiment at the Department of Energy’s Thomas Jefferson National Accelerator Facility provides a precision test of the weak force, one of four fundamental forces in nature. This result, published recently in Nature, also constrains possibilities for new particles and forces beyond our present knowledge.

"Precision measurements like this one can act as windows into a world of potential new particles that otherwise might only be observable using extremely high-energy accelerators that are currently beyond the reach of our technical capabilities," said Roger Carlini, a Jefferson Lab scientist and a co-spokesperson for the Q-weak Collaboration.

[continued on next page]
While the weak force is difficult to observe directly, its influence can be felt in our everyday world. For example, it initiates the chain of reactions that power the sun and it provides a mechanism for radioactive decays that partially heat the Earth’s core and that also enable doctors to detect disease inside the body without surgery. Now, the Q-weak Collaboration has revealed one of the weak force’s secrets: the precise strength of its grip on the proton. They did this by measuring the proton’s weak charge to high precision, which they probed using the high-quality beams available at the Continuous Electron Beam Accelerator Facility, a DOE Office of Science User Facility.

The proton’s weak charge is analogous to its more familiar electric charge, a measure of the influence the proton experiences from the electromagnetic force. These two interactions are closely related in the Standard Model, a highly successful theory that describes the electromagnetic and weak forces as two different aspects of a single force that interacts with subatomic particles.

To measure the proton’s weak charge, an intense beam of electrons was directed onto a target containing cold liquid hydrogen, and the electrons scattered from this target were detected in a precise, custom-built measuring apparatus. The key to the Q-weak experiment is that the electrons in the beam were highly polarized – prepared prior to acceleration to be mostly “spinning” in one direction, parallel or anti-parallel to the beam direction. With the direction of polarization rapidly reversed in a controlled manner, the experimenters were able to latch onto the weak interaction’s unique property of parity (akin to mirror symmetry) violation, in order to isolate its tiny effects to high precision: a different scattering rate by about 2 parts in 10 million was measured for the two beam polarization states.

The proton’s weak charge was found to be $Q_{Wp} = 0.0719 \pm 0.0045$, which turns out to be in excellent agreement with predictions of the Standard Model, which takes into account all known subatomic particles and the forces that act on them. Because the proton’s weak charge is so precisely predicted in this model, the new Q-weak result provides insight into predictions of hitherto unobserved heavy particles, such as those that may be produced by the Large Hadron Collider (LHC) at CERN in Europe or future high-energy particle accelerators.

“This very challenging experimental result is yet another clue in the world-wide search for new physics beyond our current understanding. There is ample evidence the Standard Model of Particle physics provides only an incomplete description of nature’s phenomena, but where the breakthrough will come remains elusive,” said Timothy J. Hallman, Associate Director for Nuclear Physics of the Department of Energy Office of Science. “Experiments like Q-weak are pressing ever closer to finding the answer.”

[continued on next page]
For example, the Q-weak result has set limits on the possible existence of leptoquarks, which are hypothetical particles that can reverse the identities of two broad classes of very different fundamental particles – turning quarks (the building blocks of nuclear matter) into leptons (electrons and their heavier counterparts) and vice versa.

“After more than a decade of careful work, Q-weak not only informed the Standard Model, it showed that extreme precision can enable moderate-energy experiments to achieve results on par with the largest accelerators available to science,” said Anne Kinney, Assistant Director for the Mathematical and Physical Sciences Directorate at the National Science Foundation. “Such precision will be important in the hunt for physics beyond the Standard Model, where new particle effects would likely appear as extremely tiny deviations.”

“It’s complementary information. So, if they find evidence for new physics in the future at the LHC, we can help identify what it might be, from the limits that we’re setting already in this paper,” said Greg Smith, Jefferson Lab scientist and Q-weak project manager. The Q-weak Collaboration consists of about 100 scientists and more than 20 institutions. The experiment was funded by the U.S. Department of Energy Office of Science, the National Science Foundation, the Natural Sciences and Engineering Research Council of Canada, and the Canadian Foundation for Innovation, with matching and in-kind contributions from a number of the collaborating institutions.

“SLAC Public Lecture
Making Waves in a Superconductor”

Giacomo Coslovich will present the next SLAC Public Lecture, “Making Waves in a Superconductor” on Tuesday, Jan. 29, from 7:30 to 8:30 p.m. in the Panofsky Auditorium. If you’re interested but can’t attend, we will be streaming the lecture live on SLAC’s Facebook page. A video recording will also be made available after the event. While you don’t need to register for these public lectures, seating is on a first-come, first-served basis.

Superconductors are materials in which electric current flows freely, without resistance. They are used to create the powerful magnetic fields needed to operate MRI machines and levitate high-speed trains, and have even served as building blocks for quantum computers. While most metals can become superconducting at temperatures close to absolute zero, more complex materials can superconduct at higher temperatures. Can we discover what makes these materials so special? This lecture will describe experiments at SLAC that use optical and X-ray lasers to create waves in high-temperature superconductors and observe how the materials “breathe” at the atomic level. We hope to find a path to materials that are superconducting at room temperature, making this exotic phenomenon available for everyday applications.

Giacomo Coslovich has spent his career studying complex materials using ultrafast lasers. He did his graduate research at the University of Trieste, Italy, receiving his PhD in 2011. He then took a postdoctoral position at Lawrence Berkeley National Laboratory. In 2015, he became a staff scientist at SLAC, where he studies high-temperature superconductors using SLAC’s LCLS X-ray laser.

HPS 52nd Midyear Meeting
San Diego, California
February 17-20, 2019
